

Implementation Note — Retail Sales Power BI Dashboard

1. Data Cleaning Process

- Imported Orders, Products, and Returns datasets into Power BI.
- Corrected data types for Date, Number, and Text fields.
- Removed duplicates and handled null/blank values in key columns.
- Standardized column names for consistency.

2. Data Merge Logic

- Merged Orders table with Products table using Product ID.
- Expanded Product Name, Category, Sub Category, and Unit Price.
- Merged resulting Orders table with Returns table using Order ID.
- Expanded Return ID, Return Date, Return Reason, and Return Status.

3. Derived Columns Created

- Order Month extracted from Order Date using Power Query.
- Order Year extracted from Order Date.
- Is Returned column created to identify returned orders.
- Sales Amount used as revenue field.

4. Dashboard Design Choices

- Designed 3-page structure:
 - Sales Overview
 - Product Performance
 - Returns Analysis
- Used KPI cards for key business metrics.
- Used bar, column, line, donut, and pie charts for analysis.
- Added slicers for Region, Category, and Year for interactivity.
- Maintained clean, professional layout with proper alignment.

5. Key Insights

- Identified top revenue-generating categories and products.
- Observed monthly revenue trends.
- Analyzed return patterns by region and reason.
- Compared return status distribution.

6. Conclusion

The dashboard provides a structured and interactive view of retail sales performance and returns, enabling better business decision-making.

Sales Overview Page

Product Performance Page

Returns Analysis Page

Returns by Region

Count of Returns.Return ID by Region

Returns by Reason

Count of Returns.Return ID by Returns.Return Reason

Return Status Distribution

Count of Returns.Return ID by Returns.Return Status
